| Description | | | |
| <p>An issue, already discussed in 20011 ([[20110309]]) came up again, relating to synchronization inside CCA. Synchronization can be ensured within CCA between nodes with output ports, through input-based processing strategies reacting to outputs.</p> <p>However, this is a problem with <i>sink</i> nodes without output ports, where you can't know when the node has finished processing.</p> <p>See the simple example attached, where the main program should continue not until both nodes are finished processing. Currently, this can't be achieved without taking care of this manually.</p> <p>So provide some kind of synchronization mechanism / barrier, that ensures finished processing of a node / a group of nodes / a circuit / a sub-circuit.</p> | | | |
